

### General Description

The AAT3131 is a low noise, constant frequency charge pump DC/DC converter that uses a dual mode Load Switch (1X) and fractional (1.5X) conversion to maximize efficiency for White LED applications. The device can be used to produce current levels up to 20mA in three of its outputs, and 30mA in one of its outputs to drive LEDs from a 2.7V to 5.5V input. Outputs may be operated individually or paralleled for driving higher-current LEDs. Low external parts counts (two 1µF flying capacitors and two small 1µF capacitors at  $V_{IN}$ , and OUT) make the AAT3131 ideally suited for small battery-powered applications.

AnalogicTech™'s Simple Serial Control™ (S<sup>2</sup>Cwire™) interface is used to enable, disable and set the LED drive current in two groups: the three 20mA outputs and the single 30mA output with multiple level logarithmic scales. The AAT3131 has a thermal management system to protect the device in the event of a short circuit condition at the output pin. Built-in soft-start circuitry prevents excessive inrush current during start-up. A high charge pump switching frequency enables the use of very small external capacitors. A low current shutdown feature disconnects the load from  $V_{IN}$  and reduces quiescent current to less than 1µA. The AAT3131 is available in very small 12 pin TSOPJW12 package.

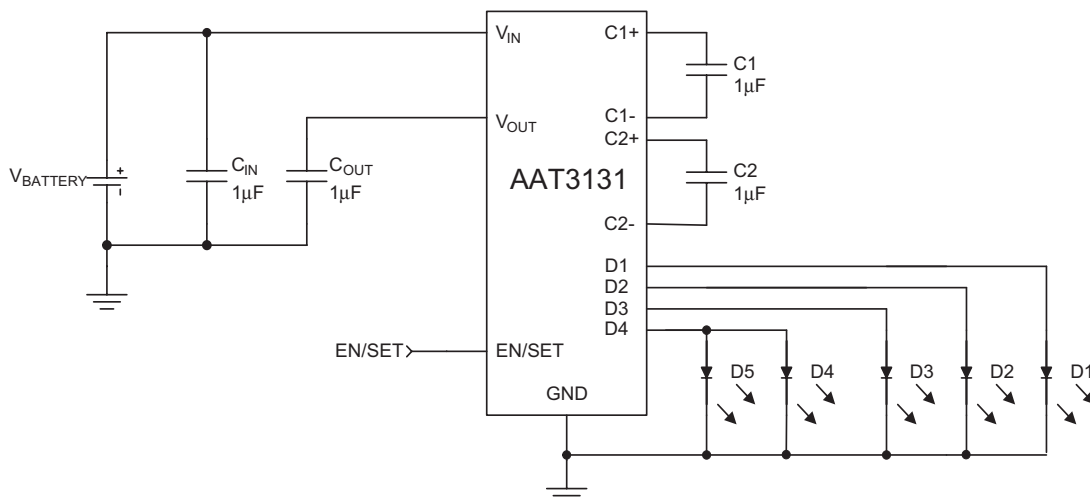

### Features

- $V_{IN}$  Range: 2.7 - 5.5 Volts
- < 1.0µA of Shutdown current
- 1.0 MHz Switching Frequency
- White LED Backlighting
- Fully Independent Display Lighting
- Dual Mode 1x and 1.5x Charge Pump for Maximum Efficiency
- Drives Low- $V_F$  & High- $V_F$  f Type LED's
- Up to three 20mA Outputs
- Single 30 mA Output
- Multi Position Logarithmic Scale with Digital Control
- Low Noise Constant Frequency Operation
- Regulated Output Current
- Automatic Soft-Start
- No Inductors
- -40 to +85°C Temperature Range
- 12 pin TSOPJW-12 package

### Applications

- White LED Backlighting
- White Photo-Flash for DSC's
- Color (RGB) Lighting
- Programmable Current Source

### Typical Application

### Pin Descriptions

Pin #	Symbol	Function
1	C2+	Flying Capacitor 2 + terminal. Connect a 1 $\mu$ F capacitor between C2+ and C2-.
2	OUT	Charge pump output. Requires 1 $\mu$ F capacitor connected between this pin and ground.
3	C1-	Flying Capacitor 1 - terminal
4	C1+	Flying Capacitor 1 + terminal. Connect a 1 $\mu$ F capacitor between C1+ and C1-.
5	D3	Current source output #4
6	D2	Current source output #3
7	D4	Current source output #2
8	D1	Current source output #1
9	EN/SET	Control Pin
10	IN	Input power supply. Requires 1 $\mu$ F capacitor connected between this pin and ground.
11	GND	Ground
12	C2-	Flying Capacitor 2 - terminal

### Pin Configuration

**TSOPJW-12**  
(Top view)

### Absolute Maximum Ratings<sup>1</sup>

Symbol	Description	Value	Units
$V_{IN}$	Input Voltage	-0.3 to 6	V
$V_{OUT}$	Charge Pump Output	-0.3 to 6	V
$F_B, V_{EN/SET}$	FB or EN/SET to GND Voltage	-0.3 to 6	V
$V_{EN/SET(MAX)}$	Maximum EN/SET to Input Voltage	$V_{IN} - 0.3$	V
$I_{OUT}^{(2)}$	Maximum DC Output Current	150	mA
$T_J$	Operating Junction Temperature Range	-40 to 150	°C
$T_{LEAD}$	Maximum Soldering Temperature (at leads, 10 sec)	300	°C

Notes:

- Stresses above those listed in Absolute Maximum Ratings may cause permanent damage to the device. Functional operation at conditions other than the operating conditions specified is not implied. Only one Absolute Maximum rating should be applied at any one time.
- Based on long-term current density limitation.

### Thermal Information

Symbol	Description	Value	Units
$\theta_{JA}$	Thermal Resistance <sup>1</sup>	160	°C/W
$P_D$	Maximum Power Dissipation <sup>1,2</sup> ( $T_A = 25^\circ\text{C}$ )	625	mW

Notes:

- Mounted on a FR4 board.
- Derate 6.25mW/°C above 25°C.

### Electrical Characteristics<sup>1</sup>

$V_{IN} = 3.5V$ ,  $C_{IN} = C_{OUT} = C1 = C2 = 1.0\mu F$ ;  $T_A = -40$  to  $85^\circ C$  unless otherwise noted. Typical values are  $T_A = 25^\circ C$ .

Symbol	Description	Conditions	Min	Typ	Max	Units
<b>Input Power Supply</b>						
$V_{IN}$	Operation Range		2.7		5.5	V
$I_{CC}$	Operating Current	$3.0 \leq V_{IN} \leq 5.5$ , Active, No Load Current		1.8	3.5	mA
$I_{SHDN}$	Shutdown Current	EN = 0			1.0	$\mu A$
$I_{DX}$	Max. Output Current D1 to D3	$3.0 \leq V_{IN} \leq 5.5$	18	20	22	mA
$I_{DX}$	Max. Output Current D4	$3.0 \leq V_{IN} \leq 5.5$	27	30	33	mA
$I_{(D-Match)}$	Current Matching between any two outputs	VD1:D3 = 3.6, $V_{IN} = 3.3V$		0.5		%
$\eta_{CP}$	Charge Pump Section Efficiency	$V_{IN} = 3.5V$ , $I_{OUT(TOTAL)} = 90mA$ , Measured from IN to OUT		93		%
<b>Charge Pump Section</b>						
$T_{SS}$	Soft start time			200		$\mu s$
$F_{CLK}$	Clock Frequency			1000		kHz
<b>EN/SET</b>						
$V_{EN(L)}$	Enable Threshold Low				0.5	V
$V_{EN(H)}$	Enable Threshold High		1.4			V
$T_{EN/SET LO}$	EN/SET low time	$V_{EN/SET} < 0.5$	0.3		75	$\mu s$
$T_{EN/SET HI}$	Minimum EN/SET high time	$V_{EN/SET} > 1.4$		50		ns
$T_{OFF}$	EN/SET Off Timeout	$V_{EN/SET} < 0.5$			500	$\mu s$
Input Current	EN/SET input leakage		-1		1	$\mu A$

**Notes:**

1. The AAT3131 is guaranteed to meet performance specification over the -40 to 85°C operating temperature range and are assured by design, characterization and correlation with statistical process controls.

### Functional Block Diagram

### Functional Description

The AAT3131 is a dual mode Load Switch (1X) and high efficiency (1.5X) fractional charge pump device intended for white LED back light applications. The fractional charge pump consists of a low dropout linear voltage regulator followed by a 1.5X charge pump with multiple current-source outputs. To maximize power conversion efficiency an internal feedback control sensing circuit monitors the voltage required on the constant current source outputs. This control circuit then sets the load switch and charge pump functions based upon the input voltage level versus the output voltage level needed. This function significantly enhances over all device efficiency when the input voltage level is greater than the voltage required at the constant current source outputs. The 1X Load Switch/1.5X charge pump mode decision is based on the voltage levels sensed on either the D1 output or the D4 output, which ever is greater. Switchover

between the 1.5X (charge-pump) operating mode and the 1X (load switch) mode occurs automatically (as a function of input and output voltages) and does not require user intervention to maintain maximum efficiency.

The AAT3131 requires only four external components: two  $1\mu\text{F}$  ceramic capacitors for the charge pump flying capacitors (C1 and C2), one  $1\mu\text{F}$  ceramic input capacitor ( $C_{\text{IN}}$ ) and one  $0.33\mu\text{F}$  to  $1\mu\text{F}$  ceramic output capacitor ( $C_{\text{OUT}}$ ). The LDO/1.5X charge pump output is converted into three (D1 to D3) constant current outputs to drive three individual LEDs with a maximum current of 20mA each, and one (D4) constant current output with a maximum current of 30mA. The current source output magnitude is controlled by the EN/SET serial data interface. The interface records rising edges of the EN/SET pin, and decodes them into 32 addresses corresponding to individual current level settings. The 32 addresses are divided

up such that outputs D1-D3 can be controlled independently of output D4. For addresses 1 to 8, 9 to 16, 17 to 24, and 25 to 32, outputs D1-D3 start at 0mA and increase from 0.5mA to 20mA in three 8dB steps and three 2.5dB steps. Output D4 remains constant over these address ranges which provides orthogonal control of the two channels. For addresses 1 to 8, D4 is set to 0mA. For addresses 9 to 16, D4 is set to 1mA. For addresses 17 to 24, D4 is set to 15mA, and for addresses 25 to 32, D4 is set to 30mA. This is summarized in Table and Figure 1.

The modulo 32 interface wraps states back to state 1 after the 32nd clock. With each EN/SET pulse, the output current changes to the next setting in the address decoding. To change settings to the previous address decoding, 31 EN/SET clock pulses are required. The counter can be clocked at speeds up to 1MHz, so intermediate states are not visible. The first rising edge of EN/SET enables the IC and initially sets the output LED currents 0mA. Additional clocks are required to set the desired current level. Once the final clock cycle is input for the desired brightness level, the EN/SET pin is held high to maintain the device output current at the programmed level. The device is disabled 500µs after the EN/SET pin transitions to a logic low state.

### Applications Information

#### Constant Current Output Level Settings

The constant current source output amplitude for output D1 to D3 and D4 are set via the serial interface according to a logarithmic scale described in the following chart and the previous section. Using a logarithmic scale, LED brightness appears linear with each increasing code count. Because the outputs D1 to D4 are true independent constant current sources, the voltage observed on any single given output will be determined by the actual forward voltage ( $V_F$ ) for the LED being driven.

Since the output current of the AAT3131 is programmable through its simple serial control (S<sup>2</sup>Cwire™), no PWM (pulse width modulation) or additional control circuitry is needed to control LED brightness. This feature greatly reduces the burden on a microcontroller or system IC to manage LED or display brightness, allowing the user to "set it, and forget it." Furthermore, with its high speed serial interface (1MHz data rate), the output current of the AAT3131 can be changed successively to brighten or dim LEDs, in smooth transitions (e.g. to fade-out) or in abrupt steps, giving the user complete programmability and real time control of LED brightness.

Output Current Level Settings

Figure 1.

**Table 1: Constant Current Source Output Programming Levels (mA)**

Address	Current Level Settings	
	D1-3	D4
1	0.0	0
2	0.5	0
3	1.3	0
4	3.3	0
5	8.3	0
6	11.1	0
7	15.0	0
8	20.0	0
9	0.0	1
10	0.5	1
11	1.3	1
12	3.3	1
13	8.3	1
14	11.1	1
15	15.0	1
16	20.0	1
17	0.0	15
18	0.5	15
19	1.3	15
20	3.3	15
21	8.3	15
22	11.1	15
23	15.0	15
24	20.0	15
25	0.0	30
26	0.5	30
27	1.3	30
28	3.3	30
29	8.3	30
30	11.1	30
31	15.0	30
32	20.0	30

### EN/SET Serial Interface (S<sup>2</sup>Cwire™)

The current source output magnitude is controlled by the EN/SET serial data interface. The interface records rising edges of the EN/SET pin, and decodes them into 32 individual current level settings summarized in the above table. The modulo 32 interface wraps states back to state 1 after the 32nd clock, so the previous state is achieved by clocking the EN/SET pin 31 times. The counter can be clocked at speeds up to 1MHz, so intermediate states are not visible. The first rising edge of EN/SET enables the IC and initially sets the output LED current to 0dB. Once the final clock cycle is input for the desired brightness level, the EN/SET pin is held high to maintain the device output current at the programmed level. The device is disabled 500µs after the EN/SET pin transitions to a logic low state. The EN/SET timing is designed to accommodate a wide range of data rates. After the first rising edge of EN/SET, the charge pump is enabled and reaches full capacity after the soft start time ( $t_{SS}$ ). During the soft start time, multiple clock pulses may be entered on the EN/SET pin to set the final output current level with a single burst of clocks. Alternatively, the EN/SET clock pulses may be entered one at a time to gradually increase the LED brightness over any desired time period. A constant current is sourced as long as EN/SET remains in a logic high state. The current source outputs are switched off after EN/SET has remained in a low state for at least the  $t_{OFF}$  timeout period.

### EN/SET Timing Diagram

### LED Selection

The AAT3131 is specifically intended for driving white LED's. However, the device design will allow the AAT3131 to drive most types of LED's with forward voltage specifications ranging from 2.0V to 4.3V. LED applications may include main and sub-LCD display backlighting, camera photo-flash applications, color (RGB) LED's, infrared (IR) diodes for remotes, and other loads benefiting from a controlled output-current generated from a varying input-voltage. Since the D1 to D6 output current sources are matched with negligible voltage dependence, the LED brightness will be matched regardless of the specific LED forward voltage ( $V_F$ ) levels.

In some instances (e.g. in high-luminous-output applications such as photo-flash) it may be necessary to drive high-VF type LED's. The low-dropout current-sources in the AAT3131 makes it capable of driving LED's with forward voltages as high as 4.3V at full current from an input supply as low as 3.0V. Outputs can be paralleled to drive high current LED's without complication.

### Device Switching Noise Performance

The AAT3131 operates at a fixed frequency of approximately 1MHz to control noise and limit harmonics that can interfere with the RF operation of cellular telephone handsets or other communication devices. Back-injected noise appearing on the input pin of the Charge Pump is 20mV peak-to-peak, typically ten times less than inductor-based DC/DC boost converter white LED backlight solutions. The AAT3131 soft-start feature prevents noise transient effects associated with in-rush currents during the start up of the charge pump circuit.

### Power Efficiency and Device Evaluation

The charge pump efficiency discussion in the following sections only account for the efficiency of the charge pump section itself. Due to the unique circuit architecture and design of the AAT3131, it is very difficult to measure efficiency in terms of a percent value comparing input power over output power.

Since the AAT3131 outputs are pure constant current sources and typically drive individual loads, it is difficult to measure the output voltage for a given output (D1 to D4) to derive an overall output power measurement. For any given application, white LED forward voltage levels can differ, yet the output drive current will be maintained as a constant.

This makes quantifying output power a difficult task when taken in the context of comparing to other white LED driver circuit topologies. A better way to quantify total device efficiency is to observe the total input power to the device for a given LED current drive level. The best white LED driver for a given application should be based on trade-offs of size, external component count, reliability, operating range and total energy usage...Not just "% efficiency".

The AAT3131 efficiency may be quantified under very specific conditions and is dependant upon the input voltage versus the output voltage seen across the loads applied to outputs D1 through D4 for a given constant current setting. Depending upon the case of  $V_{IN}$  being greater than the specific voltage seen across the load on D1 (or D4) the device will operate in "Load Switch" mode. If  $V_{IN}$  is less than the voltage required on the constant current source, the device will operate in 1.5X charge pump mode. Each of these two modes will yield

different efficiency values. One should refer to the following two sections for explanations for each operational mode.

### Load Switch Mode Efficiency

The AAT3131 load switch mode is operational at all times and functions alone to enhance device power conversion efficiency when the condition exists where  $V_{IN}$  is greater than voltage across the load connected to the constant current source outputs. When in "Load Switch" mode, the voltage conversion efficiency is defined as output power divided by input power:

$$\eta = \frac{P_{OUT}}{P_{IN}}$$

The expression to define the ideal efficiency ( $\eta$ ) can be rewritten as:

$$\eta = \frac{P_{OUT}}{P_{IN}} = \frac{V_{OUT} \times I_{OUT}}{V_{IN} \times I_{OUT}} = \frac{V_{OUT}}{V_{IN}}$$

-or-

$$\eta(\%) = 100 \left( \frac{V_{OUT}}{V_{IN}} \right)$$

### Charge Pump Section Efficiency

The AAT3131 contains a fractional charge pump which will boost the input supply voltage in the event where  $V_{IN}$  is less than the voltage required on the constant current source outputs. The efficiency ( $\eta$ ) can be simply defined as a linear voltage regulator with an effective output voltage that is equal to one and a half times the input voltage. Efficiency ( $\eta$ ) for an ideal 1.5x charge pump can typically be expressed as the output power divided by the input power.

$$\eta = \frac{P_{OUT}}{P_{IN}}$$

In addition, with an ideal 1.5x charge pump, the output current may be expressed as 2/3 of the input current. The expression to define the ideal efficiency ( $\eta$ ) can be rewritten as:

$$\eta = \frac{P_{OUT}}{P_{IN}} = \frac{V_{OUT} \times I_{OUT}}{V_{IN} \times 1.5I_{OUT}} = \frac{V_{OUT}}{1.5V_{IN}}$$

$$\eta(\%) = 100 \left( \frac{V_{OUT}}{1.5V_{IN}} \right)$$

For a charge pump with an output of 5 volts and a nominal input of 3.5 volts, the theoretical efficiency is 95%. Due to internal switching losses and IC quiescent current consumption, the actual efficiency can be measured at 93%. These figures are in close agreement for output load conditions from 1mA to 100mA. Efficiency will decrease as load current drops below 0.05mA or when level of  $V_{IN}$  approaches  $V_{OUT}$ . Refer to the Typical Characteristics section for measured plots of efficiency versus input voltage and output load current for the given charge pump output voltage options.

### Capacitor Selection

Careful selection of the four external capacitors  $C_{IN}$ , C1, C2,  $C_{OUT}$  is important because they will affect turn on time, output ripple and transient performance. Optimum performance will be obtained when low ESR (<100m $\Omega$ ) ceramic capacitors are used. In general, low ESR may be defined as less than 100m $\Omega$ . A capacitor value of 1 $\mu$ F for all four capacitors is a good starting point when choosing capacitors. If the LED current sources are only programmed for light current levels, then the capacitor size may be decreased.

### Capacitor Characteristics

Ceramic composition capacitors are highly recommended over all other types of capacitors for use with the AAT3131. Ceramic capacitors offer many advantages over their tantalum and aluminum electrolytic counterparts. A ceramic capacitor typically has very low ESR, is lowest cost, has a smaller PCB footprint and is non-polarized. Low ESR ceramic capacitors help maximize charge pump transient response. Since ceramic capacitors are non-polarized, they are not prone to incorrect connection damage.

### Equivalent Series Resistance (ESR)

ESR is an important characteristic to consider when selecting a capacitor. ESR is a resistance internal to a capacitor, which is caused by the leads, internal connections, size or area, material composition and ambient temperature. Capacitor ESR is typically measured in milliohms for ceramic capacitors and can range to more than several ohms for tantalum or aluminum electrolytic capacitors.

### Ceramic Capacitor Materials

Ceramic capacitors less than 0.1 $\mu$ F are typically made from NPO or COG materials. NPO and COG materials typically have tight tolerance and are stable over temperature. Large capacitor values are typically composed of X7R, X5R, Z5U or Y5V dielectric materials. Large ceramic capacitors, typically greater than 2.2 F are often available in low cost Y5V and Z5U dielectrics, but capacitors greater than 1 $\mu$ F are typically not required for AAT3131 applications.

Capacitor area is another contributor to ESR. Capacitors that are physically large will have a lower ESR when compared to an equivalent material smaller capacitor. These larger devices can improve circuit transient response when compared to an equal value capacitor in a smaller package size.

### Thermal Protection

The AAT3131 has a thermal protection circuit that will shut down the internal LDO and charge pump if the die temperature rises above the thermal limit as is the case during a short circuit of the OUT pin.

### Driving Multiple LED's, White LED display module back lights and individual LED's connected in parallel

The AAT3131 D1 to D4 outputs are true constant current sources capable of driving up to 20mA (D1 - D3) or 30mA (D4) each over the operation input voltage range. Since these outputs are true constant current sources, they may be connected in parallel to drive a single power output. Any combination of outputs (D1 to D4) may be connected in parallel. The maximum total output current is a sum of how many current sources are parallel connected. This feature is particularly useful to power pre-manufactured display modules which are pre-wired

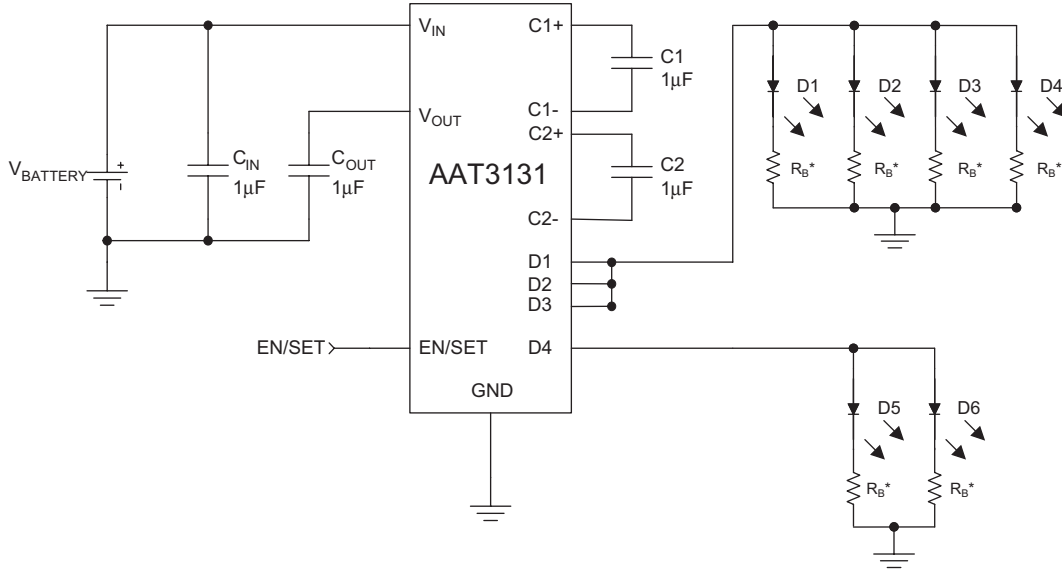

with white LED backlights connected in a parallel circuit configuration. Any combination of outputs may be connected in parallel to drive groups of LED's. The AAT3131 internal current source reference circuit bases feedback from current sensed on the D1 and D4 outputs. For best operation, the only requirement for this type of application is the outputs D1 and D5 should always be connected to the load circuit.

The AAT3131 may be used to drive multiple LED's having differing forward voltages. Using feedback techniques, the current in D1 to D3 output currents sources are referenced to the current in the LED connected to D1. Current source output D4 is its own reference. If all LED's are of similar type, the diodes will be matched in current, maintaining uniform LED brightness despite variations in manufacturer, production, etc.

If however, the diodes are dramatically different in type comprising a mix of high-VF type and low-VF-type LED's, the AAT3131 has the capability to optimally drive up to four LED's of one-type and up to two LED's of another type simultaneously. Such a feature can be useful for driving different color LED's; driving both display backlight and photo-flash LED's; or for driving main-LCD and sub-LCD display LED backlights from a single Charge Pump IC. For example, when driving independent RGB LED's, the green and blue type LED's typically require a high VF to operate (e.g. 3.7V) while the red LED needs a low forward voltage (e.g. 2V). By connecting the green and blue diodes to outputs D1 to D3 and the red diodes to D4, good control and uniformity in brightness is maintained despite the 2V difference in the diode forward voltages. The AAT3131 determines if the 1.5X charge pump circuit is needed based on the voltage on D1 and D4, whichever one is higher. If adequate voltage is available to drive the higher voltage LED (of output D1 or D4) without the charge pump running, the IC automatically switches into load switch (1X) mode to maximize efficiency.

Similarly, if a 4V photo-flash LED-array is connected to outputs D1 through D3 (with the outputs shorted together) and two 3.3V sub-LCD-display backlight LED's are connected to output D4, then the AAT3131 can optimally drive each set of LED's at the programmed current level (see application schematics).

### Additional Application Circuit

\*In some applications, white LED forward voltages ( $V_f$ ) can vary significantly. Ballast resistors between the LED cathodes and ground are recommended for balancing the forward voltage differences. The ballast resistor value may be approximated by the following equation:

$$R_B = \frac{V_{SOURCE} - V_f}{I_f}$$

### AAT3131 Driving Two Groups of Paralleled White LED's (e.g. main-LCD & sub-LCD backlights)
