

CAT1024, CAT1025

Supervisory Circuits with I²C Serial 2K CMOS EEPROM and Manual Reset

FEATURES

- Precision power supply voltage monitor
 - 5V, 3.3V and 3V systems
 - Five threshold voltage options
- Active high or low reset
 - Valid reset guaranteed at $V_{CC}=1V$
- 400kHz I²C bus
- 2.7V to 5.5V operation
- Low power CMOS technology
- 16-Byte page write buffer
- Built-in inadvertent write protection
 - WP pin (CAT1025)
- 1,000,000 Program/Erase cycles
- Manual reset input
- 100 year data retention
- 8-pin DIP, SOIC, TSSOP, TDFN (MSOP (3x4.9mm) & 3x3mm foot prints) or MSOP packages
- Automotive, extended automotive and industrial temperature ranges

DESCRIPTION

The CAT1024 and CAT1025 are complete memory and supervisory solutions for microcontroller-based systems. A 2kbit serial EEPROM memory and a system power supervisor with brown-out protection are integrated together in low power CMOS technology. Memory interface is via a 400kHz I²C bus.

The CAT1025 provides a precision V_{CC} sense circuit and two open drain outputs: one (RESET) drives high and the other (RESE \bar{T}) drives low whenever V_{CC} falls below the reset threshold voltage. The CAT1025 also has a Write Protect input (WP). Write operations are disabled if WP is connected to a logic high.

The CAT1024 also provides a precision V_{CC} sense circuit, but has only a RESE \bar{T} output and does not have a Write Protect input.

The power supply monitor and reset circuit protect memory and system controllers during power up/down and against brownout conditions. Five reset threshold

voltages support 5V, 3.3V and 3V systems. If power supply voltages are out of tolerance reset signals become active, preventing the system microcontroller, ASIC or peripherals from operating. Reset signals become inactive typically 200 ms after the supply voltage exceeds the reset threshold level. With both active high and low reset signals, interface to microcontrollers and other ICs is simple. In addition, the RESE \bar{T} pin or a separate input, MR, can be used as an input for push-button manual reset capability.

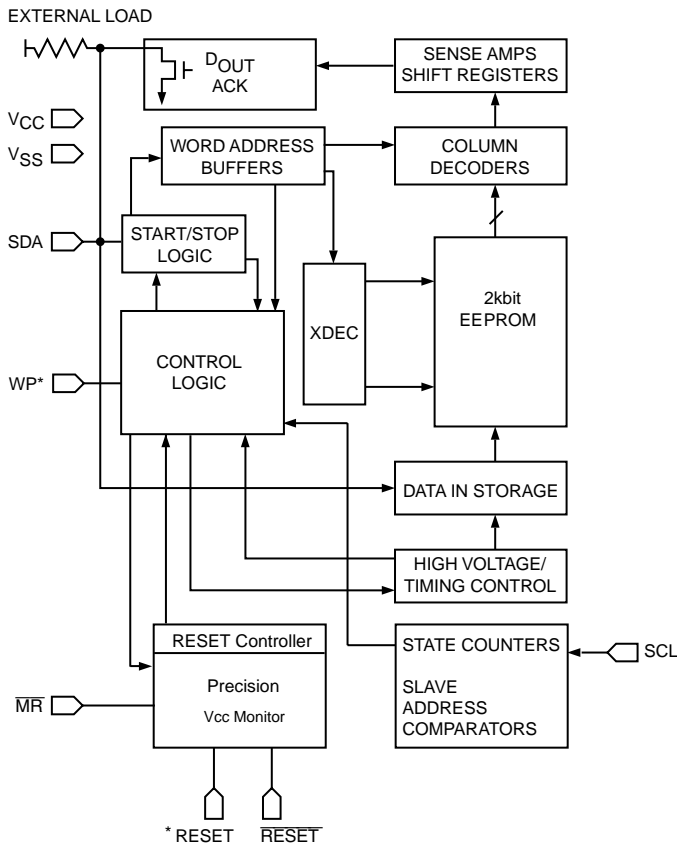

The CAT1024/25 memory features a 16-byte page. In addition, hardware data protection is provided by a V_{CC} sense circuit that prevents writes to memory whenever V_{CC} falls below the reset threshold or until V_{CC} reaches the reset threshold during power up.

Available packages include an 8-pin DIP and a surface mount 8-pin SO, 8-pin TSSOP, 8-pin TDFN and 8-pin MSOP packages. The TDFN package thickness is 0.8mm maximum. TDFN footprint options are 3x3mm or 3x4.9mm (MSOP pad layout).

PIN CONFIGURATION

BLOCK DIAGRAM — CAT1024, CAT1025

*CAT1025 Only

Threshold Voltage Options

Part Dash Number	Minimum Threshold	Maximum Threshold
-45	4.50	4.75
-42	4.25	4.50
-30	3.00	3.15
-28	2.85	3.00
-25	2.55	2.70

PIN FUNCTIONS

Pin Name	Function
NC	No Connect
RESET	Active Low Reset Input/Output
Vss	Ground
SDA	Serial Data/Address
SCL	Clock Input
RESET	Active High Reset Output (CAT1025 only)
Vcc	Power Supply
WP	Write Protect (CAT1025 only)
MR	Manual Reset Input

OPERATING TEMPERATURE RANGE

Industrial	-40°C to 85°C
Automotive	-40°C to 105°C
Extended	-40°C to 125°C

PIN DESCRIPTION

RESET/RESET: RESET OUTPUTS (RESET CAT1025 Only)

These are open drain pins and $\overline{\text{RESET}}$ can be used as a manual reset trigger input. By forcing a reset condition on the pin the device will initiate and maintain a reset condition. The RESET pin must be connected through a pull-down resistor, and the $\overline{\text{RESET}}$ pin must be connected through a pull-up resistor.

SDA: SERIAL DATA ADDRESS

The bidirectional serial data/address pin is used to transfer all data into and out of the device. The SDA pin is an open drain output and can be wire-ORed with other open drain or open collector outputs.

SCL: SERIAL CLOCK

Serial clock input.

MR: MANUAL RESET INPUT

Manual Reset input is a debounced input that can be connected to an external source for Manual Reset. Pulling the MR input low will generate a Reset condition. Reset outputs are active while $\overline{\text{MR}}$ input is low and for the reset timeout period after $\overline{\text{MR}}$ returns to high. The input has an internal pull up resistor.

WP (CAT1025 Only): WRITE PROTECT INPUT

When tied to V_{SS} or left unconnected write operations to the entire array are allowed. When tied to V_{CC} , the entire array is protected. This input has an internal pull down resistor.

ABSOLUTE MAXIMUM RATINGS

Temperature Under Bias	-55°C to +125°C
Storage Temperature	-65°C to +150°C
Voltage on any Pin with Respect to Ground ⁽¹⁾	-2.0V to +V _{CC} +2.0V
V _{CC} with Respect to Ground	-2.0V to +7.0V
Package Power Dissipation Capability (T _A = 25°C)	1.0W
Lead Soldering Temperature (10 secs)	300°C
Output Short Circuit Current ⁽²⁾	100 mA

Stresses above those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions outside of those listed in the operational sections of this specification is not implied. Exposure to any absolute maximum rating for extended periods may affect device performance and reliability.

Note:

- (1) The minimum DC input voltage is -0.5V. During transitions, inputs may undershoot to -2.0V for periods of less than 20 ns. Maximum DC voltage on output pins is V_{CC} +0.5V, which may overshoot to V_{CC} +2.0V for periods of less than 20 ns.
- (2) Output shorted for no more than one second. No more than one output shorted at a time.

D.C. OPERATING CHARACTERISTICS

V_{CC} = +2.7V to +5.5V and over the recommended temperature conditions unless otherwise specified.

Symbol	Parameter	Test Conditions	Min	Typ	Max	Units
I _{LI}	Input Leakage Current	V _{IN} = GND to V _{CC}	-2		10	μA
I _{LO}	Output Leakage Current	V _{IN} = GND to V _{CC}	-10		10	μA

$I_{LTH}^{(1)(2)}$	Latch-Up	JEDEC Standard 17	100		mA

DEVICE OPERATION

Reset Controller Description

The CAT1024/25 precision RESET controllers ensure correct system operation during brownout and power up/down conditions. They are configured with open drain RESET outputs.

During power-up, the RESET outputs remain active until V_{CC} reaches the V_{TH} threshold and will continue driving the outputs for approximately 200ms (t_{PURST}) after reaching V_{TH} . After the t_{PURST} timeout interval, the device will cease to drive the reset outputs. At this point the reset outputs will be pulled up or down by their respective pull up/down resistors.

During power-down, the RESET outputs will be active when V_{CC} falls below V_{TH} . The \overline{RESET} output will be valid so long as V_{CC} is $>1.0V$ (V_{RVALID}). The device is designed to ignore the fast negative going V_{CC} transient pulses (glitches).

Reset output timing is shown in Figure 1.

Manual Reset Operation

The \overline{RESET} pin can operate as reset output and manual reset input. The input is edge triggered; that is, the \overline{RESET} input will initiate a reset timeout after detecting a high to low transition.

When \overline{RESET} I/O is driven to the active state, the 200 msec timer will begin to time the reset interval. If external reset is shorter than 200 ms, Reset outputs will remain active at least 200 ms.

CAT1024/25 also have a separate manual reset input. Driving the \overline{MR} input low by connecting a pushbutton (normally open) from \overline{MR} pin to GND will generate a reset condition. The input has a internal pull up resistor.

Reset remains asserted while \overline{MR} is low and for the Reset Timeout period after \overline{MR} input has gone high.

Glitches shorter than 100 ns on \overline{MR} input will not generate a reset pulse. No external debouncing circuits are required. Manual reset operation using \overline{MR} input is shown in Figure 2.

Hardware Data Protection

The CAT1024/25 family has been designed to solve many of the data corruption issues that have long been associated with serial EEPROMs. Data corruption occurs when incorrect data is stored in a memory location which is assumed to hold correct data.

Whenever the device is in a Reset condition, the embedded EEPROM is disabled for all operations,

including write operations. If the Reset output(s) are active, in progress communications to the EEPROM are aborted and no new communications are allowed. In this condition an internal write cycle to the memory can not be started, but an in progress internal non-volatile memory write cycle can not be aborted. An internal write cycle initiated before the Reset condition can be successfully finished if there is enough time (5ms) before V_{CC} reaches the minimum value of 2V.

In addition, the CAT1025 includes a Write Protection Input which when tied to V_{CC} will disable any write operations to the device.

Figure 1. RESET Output Timing

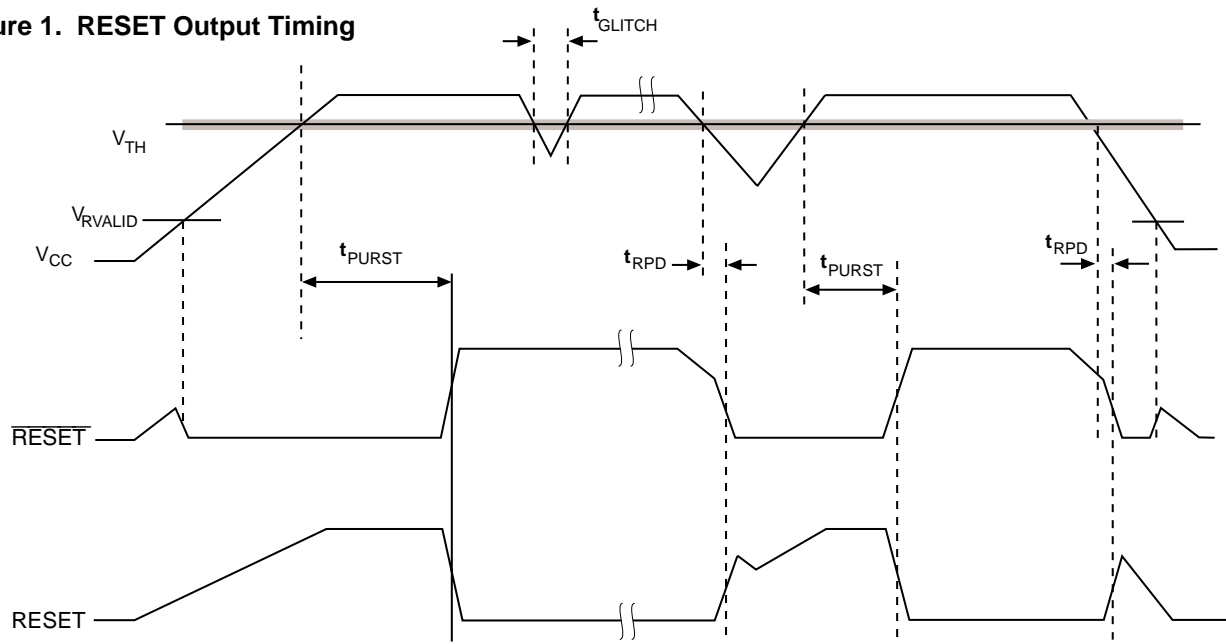

Figure 2. \overline{MR} Operation and Timing

EMBEDDED EEPROM OPERATION

The CAT1024 and CAT1025 feature a 2kbit embedded serial EEPROM that supports the I²C Bus data transmission protocol. This Inter-Integrated Circuit Bus protocol defines any device that sends data to the bus to be a transmitter and any device receiving data to be a receiver. The transfer is controlled by the Master device which generates the serial clock and all START and STOP conditions for bus access. Both the Master device and Slave device can operate as either transmitter or receiver, but the Master device controls which mode is activated.

I²C Bus Protocol

The features of the I²C bus protocol are defined as follows:

- (1) Data transfer may be initiated only when the bus is not busy.
- (2) During a data transfer, the data line must remain stable whenever the clock line is high. Any changes in the data line while the clock line is high will be interpreted as a START or STOP condition.

START Condition

The START Condition precedes all commands to the device, and is defined as a HIGH to LOW transition of

SDA when SCL is HIGH. The CAT1024/25 monitors the SDA and SCL lines and will not respond until this condition is met.

STOP Condition

A LOW to HIGH transition of SDA when SCL is HIGH determines the STOP condition. All operations must end with a STOP condition.

DEVICE ADDRESSING

The Master begins a transmission by sending a START condition. The Master sends the address of the particular slave device it is requesting. The four most significant bits of the 8-bit slave address are programmable in metal and the default is 1010.

The last bit of the slave address specifies whether a Read or Write operation is to be performed. When this bit is set to 1, a Read operation is selected, and when set to 0, a Write operation is selected.

After the Master sends a START condition and the slave address byte, the CAT1024/25 monitors the bus and responds with an acknowledge (on the SDA line) when its address matches the transmitted slave address. The CAT1024/25 then performs a Read or Write operation depending on the R/W bit.

Figure 3. Bus Timing

Figure 4. Write Cycle Timing

ACKNOWLEDGE

After a successful data transfer, each receiving device is required to generate an acknowledge. The acknowledging device pulls down the SDA line during the ninth clock cycle, signaling that it received the 8 bits of data.

The CAT1024/25 responds with an acknowledge after receiving a START condition and its slave address. If the device has been selected along with a write operation, it responds with an acknowledge after receiving each 8-bit byte.

When the CAT1024/25 begins a READ mode it transmits 8 bits of data, releases the SDA line and monitors the line for an acknowledge. Once it receives this acknowledge, the CAT1024/25 will continue to transmit data. If no acknowledge is sent by the Master, the device terminates data transmission and waits for a STOP condition.

WRITE OPERATIONS

Byte Write

In the Byte Write mode, the Master device sends the START condition and the slave address information (with the R/W bit set to zero) to the Slave device. After the Slave generates an acknowledge, the Master sends a 8-bit address that is to be written into the address pointers of the device. After receiving another acknowledge from the Slave, the Master device transmits the data to be written into the addressed memory location. The CAT1024/25 acknowledges once more and the Master generates the STOP condition. At this time, the device begins an internal programming cycle to non-volatile memory. While the cycle is in progress, the device will not respond to any request from the Master device.

Figure 5. Start/Stop Timing

Figure 6. Acknowledge Timing

Figure 7. Slave Address Bits

Default Configuration

1	0	1	0	0	0	0	R/W
---	---	---	---	---	---	---	-----

Page Write

The CAT1024/25 writes up to 16 bytes of data in a single write cycle, using the Page Write operation. The page write operation is initiated in the same manner as the byte write operation, however instead of terminating after the initial byte is transmitted, the Master is allowed to send up to 15 additional bytes. After each byte has been transmitted, the CAT1024/25 will respond with an acknowledge and internally increment the lower order address bits by one. The high order bits remain unchanged.

If the Master transmits more than 16 bytes before sending the STOP condition, the address counter 'wraps around,' and previously transmitted data will be overwritten.

When all 16 bytes are received, and the STOP condition has been sent by the Master, the internal programming cycle begins. At this point, all received data is written to the CAT1024/25 in a single write cycle.

Figure 8. Byte Write Timing

Figure 9. Page Write Timing

Acknowledge Polling

Disabling of the inputs can be used to take advantage of the typical write cycle time. Once the stop condition is issued to indicate the end of the host's write operation, the CAT1024/25 initiates the internal write cycle. ACK polling can be initiated immediately. This involves issuing the start condition followed by the slave address for a write operation. If the device is still busy with the write operation, no ACK will be returned. If a write operation has completed, an ACK will be returned and the host can then proceed with the next read or write operation.

WRITE PROTECTION

The Write Protection feature (CAT1025 only) allows the user to protect against inadvertent memory array programming. If the WP pin is tied to V_{CC}, the entire

memory array is protected and becomes read only. The CAT1025 will accept both slave and byte addresses, but the memory location accessed is protected from programming by the device's failure to send an acknowledge after the first byte of data is received.

Read Operations

The READ operation for the CAT1024/25 is initiated in the same manner as the write operation with one exception, that R/W bit is set to one. Three different READ operations are possible: Immediate/Current Address READ, Selective/Random READ and Sequential READ.

Figure 10. Immediate Address Read Timing

Immediate/Current Address Read

The CAT1024 and CAT1025 address counter contains the address of the last byte accessed, incremented by one. In other words, if the last READ or WRITE access was to address N, the READ immediately following would access data from address N+1. For all devices, N=E=255. The counter will wrap around to Zero and continue to clock out valid data for the 2K devices. After the CAT1024 and CAT1025 receives its slave address information (with the R/W bit set to one), it issues an acknowledge, then transmits the 8-bit byte requested. The master device does not send an acknowledge, but will generate a STOP condition.

Selective/Random Read

Selective/Random READ operations allow the Master device to select at random any memory location for a READ operation. The Master device first performs a 'dummy' write operation by sending the START condition, slave address and byte addresses of the location it wishes to read. After the CAT1024 and CAT1025 acknowledges, the Master device sends the START condition and the slave address again, this time with the R/W bit set to one. The CAT1024 and CAT1025 then responds with its acknowledge and sends the 8-bit byte requested. The master device does not send an

acknowledge but will generate a STOP condition.

Sequential Read

The Sequential READ operation can be initiated by either the Immediate Address READ or Selective READ operations. After the CAT1024 and CAT1025 sends the initial 8-bit byte requested, the Master will responds with an acknowledge which tells the device it requires more data. The CAT1024 and CAT1025 will continue to output an 8-bit byte for each acknowledge, thus sending the STOP condition.

The data being transmitted from the CAT1024 and CAT1025 is sent sequentially with the data from address N followed by data from address N+1. The READ operation address counter increments all of the CAT1024 and CAT1025 address bits so that the entire memory array can be read during one operation.
