**1024 x 4 CMOS RAM**

**Features**

- Low Power Standby . . . . . **125 $\mu$ W Max**
- Low Power Operation . . . . . **35mW/MHz Max**
- Data Retention . . . . . **at 2.0V Min**
- TTL Compatible Input/Output
- Common Data Input/Output
- Three-State Output
- Standard JEDEC Pinout
- Fast Access Time. . . . . **120/200ns Max**
- 18 Pin Package for High Density
- On-Chip Address Register
- Gated Inputs - No Pull Up or Pull Down Resistors Required

**Description**

The HM-6514 is a 1024 x 4 static CMOS RAM fabricated using self-aligned silicon gate technology. The device utilizes synchronous circuitry to achieve high performance and low power operation.

On-chip latches are provided for addresses allowing efficient interfacing with microprocessor systems. The data output can be forced to a high impedance state for use in expanded memory arrays.

Gated inputs allow lower operating current and also eliminate the need for pull up or pull down resistors. The HM-6514 is a fully static RAM and may be maintained in any state for an indefinite period of time.

Data retention supply voltage and supply current are guaranteed over temperature.

TIME REFERENCE	INPUTS			DATA I/O DQ	FUNCTION
	E-bar	W-bar	A		
-1	H	X	X	Z	Memory Disabled
0		H	V	Z	Cycle Begins, Addresses are Latched

3		H	X	V	Read Accomplished
4	H	X	X	Z	Prepare for Next Cycle (Same as -1)
5		H	V	Z	Cycle Ends, Next Cycle Begins (Same as 0)

The address information is latched in the on-chip registers on the falling edge of E-bar (T = 0). Minimum address set up and hold time requirements must be met. After the required hold time, the addresses may change state without affecting device operation. During time (T = 1) the output becomes

enabled, but data is not valid until during time (T = 2). W-bar must remain high throughout the read cycle. After the output data has been read, E-bar may return high (T = 3). This will disable the output buffer and all inputs, and ready the RAM for the next memory cycle (T = 4).

FIGURE 2. WRITE CYCLE

TRUTH TABLE

TIME REFERENCE	INPUTS			DQ	FUNCTION
	$\bar{E}$	$\bar{W}$	A		
-1	H	X	X	Z	Memory Disabled
0		X	V	Z	Cycle Begins, Addresses are Latched
1	L	L	X	Z	Write Period Begins
2	L		X	V	Data In is Written
3		H	X	Z	Write Completed
4	H	X	X	Z	Prepare for Next Cycle (Same as -1)
5		X	V	Z	Cycle Ends, Next Cycle Begins (Same as 0)

The write cycle is initiated by the falling edge of  $\bar{E}$  ( $T = 0$ ), which latches the address information in the on-chip registers. There are two basic types of write cycles, which differ in the control of the common data-in/data-out bus.

Case 1:  $\bar{E}$  falls before  $\bar{W}$  falls

The output buffers may become enabled (reading) if  $\bar{E}$  falls before  $\bar{W}$  falls.  $\bar{W}$  is used to disable (three-state) the outputs so input data can be applied. TWLDV must be met to allow the  $\bar{W}$  signal time to disable the outputs before applying input data. Also, at the end of the cycle the outputs may become active if  $\bar{W}$  rises before  $\bar{E}$ . The RAM outputs and all inputs will three-state after  $\bar{E}$  rises (TEHQZ). In this type of write cycle TWLEL and TEHWH may be ignored.

Case 2:  $\bar{E}$  falls equal to or after  $\bar{W}$  falls, and  $\bar{E}$  rises before or equal to  $\bar{W}$  rising

This  $\bar{E}$  and  $\bar{W}$  control timing will guarantee that the data outputs will stay disabled throughout the cycle, thus, simplifying the data input timing. TWLEL and TEHWH must be met, but TWLDV becomes meaningless and can be ignored. In this cycle TDVWH and TWHDX become TDVEH and TEHDX. In other words, reference data setup and hold times to the  $\bar{E}$  rising edge.

	IF	OBSERVE	IGNORE
Case 1	$\bar{E}$ falls before $\bar{W}$	TWLDV	TWLEL
Case 2	$\bar{E}$ falls after $\bar{W}$ and $\bar{E}$ rises before $\bar{W}$	TWLEL TEHWH	TWLDV TWHDX

If a series of consecutive write cycles are to be performed,  $\bar{W}$  may be held low until all desired locations have been written (an extension of Case 2).
